

**DKA RESUSCITATION**

**STEP 1**

- 0.9% NS 0.9% NS 2-3 L OVER 1-3 HOURS
- NOT FIRST 0.45% IS SECOND-STEP FLUID
- PRECIPITANTS: INFECTION (most common), MISSED INSULIN, MI, STROKE, SGLT2i
- STEP PIPELINE: DEEP, RAPID KUSSMAUL BREATHING; FRUITY ACETONE BREATH
- ADD DEXTROSE WHEN GLUCOSE REACHES 250 mg/dL
- NAUSEA, VOMITING; VOMITING; ABDOMINAL PAIN

**STEP 2**

- 0.1 U/kg IV BOLUS → 0.1 U/kg/h INFUSION
- GOAL: DROP GLUCOSE 50-100 mg/dL/h
- PAUSE BUTTON

**STEP 3**

**K<sup>+</sup> MANAGEMENT PANEL**

- K<sup>+</sup> <3.3 meq/L: STOP SIGN, HOLD INSULIN, REPLACE K<sup>+</sup> FIRST - FATAL HYPOKALEMIA RISK
- K<sup>+</sup> 3.3-5.0: GIVE BOTH TOGETHER
- K<sup>+</sup> >5.0: START INSULIN, HOLD K<sup>+</sup>, MONITOR CLOSELY

**GLUCOSE**

- 250-600 >600
- NHS: HIGH, NONE/MILD

**COMPARISON**

- GLUCOSE: 250-600 >600
- pH: 6.8-7.3 >7.30 (not acidosic)
- KETONE: HIGH, NONE/MILD
- MENTAL STATUS: mild ↓ severe ↓
- HYPOTENSION
- TACHYCARDIA

**HHS RESUSCITATION**

**HHS FLUID TREATMENT**

- TOTAL 8-12 L DEFICIT
- TOTAL DEFICIT 8-12 L (MUCH MORE THAN DKA)
- 0.9% NS 2-3 L over first 2-3 hours
- FLUIDS FIRST - NOT INSULIN FIRST
- REPLACE SLOWLY TOO RAPID = WORSENS NEUROLOGIC STATUS
- 0.45% saline
- 0.45% SALINE SWITCH Na<sup>+</sup> >150
- SEVERE ALTERED MENTAL STATUS - MORE THAN DKA
- SUNKEN EYES DRY MUCOUS MEMB.
- THESE ARE ABSENT IN HHS
- \* HHH - High glucose, Hypersmolar, Hoarse dehydration

**EUGLYCEMIC DKA CORNER**

- FULL DKA ALARM: High keto, Low pH, High gap
- NORMAL DO NOT BE FOOLED
- ANION GAP CALCULATOR: CHECK ANION GAP FIRST, NOT GLUCOSE, NOT INR
- ANION GAP CALCULATOR: ANION GAP, DEXTROSE ADDED EARLY
- Stop SGLT2i → IV fluids → insulin → MUST ADD DEXTROSE BECAUSE GLUCOSE IS NORMAL
- RESOLUTION = BICARBONATE CORRECTION NOT GLUCOSE

**INPATIENT MANAGEMENT STATION**

- INPATIENT TARGET: 140-180 mg/dL
- <110 mg/dL ⚠️
- NICE-SUGAR TRIAL: TIGHT CONTROL <110 = ↑ MORTALITY
- NEVER SLIDING SCALE ALONE NO BASAL = DANGEROUS
- PROPER BASAL-BOLUS
- NEVER SLIDING SCALE ALONE
- Long-acting, Rapid-acting, Correction

**STERIOD DM CORNER**

- GLUCOSE: STERIOD-INDUCED DM: POSTPRANDIAL DOMINANT
- GLUCOSE: MORNING NPH
- PEAKS 4-6h
- IF FPG >200 mg/dL → ORAL AGENTS INSUFFICIENT → INSULIN

## 1. Step 1 Fluids first

### WHAT YOU SEE

Far-LEFT STEP 1: first IV bag, 0.9% NS / LR isotonic, 2-1 L over 1-3 hours (first fluid)

### WHAT IT ENCODES

Rung 1 (always first): isotonic IV fluids — 0.9% NS (or LR) at ~15-20 mL/kg or 1-1.5 L in the first hour. Deficits: DKA ~3-6 L, HHS ~8-12 L (more profound dehydration → more aggressive resuscitation). Fluids alone lower glucose substantially via hemodilution and restored renal perfusion/clearance, and they restore hemodynamics before insulin shifts fluid/K<sup>+</sup> intracellularly.

### BOARD TRAP

WRONG: 'Start the insulin drip immediately on arrival.' Insulin before volume resuscitation worsens hypovolemia and can cause fatal hypokalemia. Discriminator: fluids are rung 1 — insulin waits for volume + a checked K<sup>+</sup>.

## 2. Correct Na -> switch to half-NS

### WHAT YOU SEE

Far-LEFT: second IV bag 0.45% NS = NOT FIRST, second-step fluid after Na correction

### WHAT IT ENCODES

After the initial NS bolus, choose maintenance fluid by the CORRECTED sodium (add ~1.6-2.4 mEq Na per 100 mg/dL glucose above normal, since hyperglycemia dilutes measured Na). If corrected Na is normal/high → switch to 0.45% (half) NS to give free water; if corrected Na is low → continue 0.9% NS. Goal: replace the free-water deficit while avoiding too-rapid osmolar shifts.

### BOARD TRAP

WRONG: 'The measured serum Na is low, so give hypotonic fluids and treat hyponatremia.' The low measured Na is usually a dilutional artifact of hyperglycemia — correct it first. Discriminator: act on the CORRECTED sodium, not the raw value.

## 3. Step 2 Potassium before insulin

### WHAT YOU SEE

Bottom-LEFT STEP 3 header: K<sup>+</sup> MANAGEMENT PANEL (potassium checked/managed before insulin)

### WHAT IT ENCODES

Rung 2: check serum potassium BEFORE starting insulin, because insulin (and correction of acidosis) drives K<sup>+</sup> into cells and can precipitate life-threatening hypokalemia/arrhythmia. Total-body K<sup>+</sup> is depleted in every DKA/HHS patient regardless of the serum value, due to osmotic-diuresis losses and transcellular shift. Recheck K<sup>+</sup> q2h during treatment.

### BOARD TRAP

WRONG: 'Glucose is dangerously high, so start insulin first and check potassium afterward.' Insulin given before knowing K<sup>+</sup> can cause fatal hypokalemia. Discriminator: K<sup>+</sup> is checked and managed BEFORE the insulin drip — always.

## 4. K traffic light <3.3 hold insulin

### WHAT YOU SEE

RED light K bag, K<sup>+</sup> <3.3 mEq/L: STOP SIGN, HOLD INSULIN, replace K first - fatal hypokalemia risk

### WHAT IT ENCODES

RED light — K<sup>+</sup> <3.3 mEq/L: HOLD insulin and replete potassium first (give ~10-20 mEq/hr IV) until K<sup>+</sup> ≥3.3. Insulin here would shift the already-low K<sup>+</sup> intracellularly and cause fatal hypokalemia/arrhythmia. Resume insulin only once K<sup>+</sup> has crossed back above 3.3.

### BOARD TRAP

WRONG: 'K<sup>+</sup> is 3.0 but glucose is 500 — start insulin anyway, the hyperglycemia is the emergency.' Hypokalemia is the more immediate killer (arrhythmia). Discriminator: K<sup>+</sup> <3.3 → replete potassium FIRST, hold insulin, no exceptions.

## 5. K 3.3-5.2 give K with fluids

### WHAT YOU SEE

YELLOW light K bag, K<sup>+</sup> 3.3-5.0 mEq/L: GIVE K WITH FLUIDS / insulin together

### WHAT IT ENCODES

YELLOW light — K<sup>+</sup> 3.3-5.2 mEq/L: proceed with insulin AND add 20-30 mEq potassium to each liter of IV fluid to keep K<sup>+</sup> in the 4-5 range, anticipating the fall as insulin acts. This is the most common scenario at presentation. Continue cardiac monitoring and q2h K<sup>+</sup> checks.

### BOARD TRAP

WRONG: 'K<sup>+</sup> is normal at 4.5, so no potassium replacement is needed.' A 'normal' serum K<sup>+</sup> in DKA still means total-body depletion and will drop with insulin. Discriminator: in the 3.3-5.2 window, give K<sup>+</sup> WITH the insulin — a normal value is not reassurance.

## 6. K >5.2 no K yet

### WHAT YOU SEE

GREEN light K bag, K<sup>+</sup> >5.0 mEq/L: NO K yet, start insulin, recheck

### WHAT IT ENCODES

GREEN light — K<sup>+</sup> >5.2 mEq/L: start insulin and fluids but do NOT add potassium yet; recheck K<sup>+</sup> in ~2 hours. Insulin and rehydration will bring the elevated serum K<sup>+</sup> down (and total-body K<sup>+</sup> is still low, so it will eventually need replacement). Begin K<sup>+</sup> once it falls below 5.2 and urine output is confirmed.

### BOARD TRAP

WRONG: 'K<sup>+</sup> is 5.5 — treat the hyperkalemia with kayexalate/aggressive measures.' The hyperkalemia is from transcellular shift and self-corrects with insulin/fluids. Discriminator: hold K<sup>+</sup> replacement (don't aggressively lower it either) and recheck — insulin itself is the treatment.

## 7. Step 3 Insulin infusion

### WHAT YOU SEE

Far-LEFT STEP 2: insulin syringe/pump, 0.1 U/kg/h IV infusion, goal drop 50-100 mg/dL/h

### WHAT IT ENCODES

Rung 3: IV regular insulin infusion at 0.1 U/kg/hr (with or without an initial 0.1 U/kg bolus; the bolus is OMITTED in children to reduce cerebral-edema risk). Target a glucose fall of 50-100 mg/dL/hr; if glucose doesn't drop ~10% in the first hour, increase the rate or reassess fluids. Insulin's real job is to halt lipolysis/ketogenesis and close the anion gap.

### BOARD TRAP

WRONG: 'Use intermittent subcutaneous regular insulin boluses for severe DKA.' Variable SC absorption in a dehydrated patient is unreliable — IV infusion is standard for severe DKA/HHS. Discriminator: continuous IV insulin (not SC) until the gap closes.

## 8. Step 4 Add dextrose at ~200

### WHAT YOU SEE

Center-bottom: ADD DEXTROSE when glucose reaches ~200 (euglycemic-DKA corner), continue insulin

### WHAT IT ENCODES

Rung 4: when glucose reaches ~200 mg/dL (DKA) or ~250-300 (HHS), add D5 (e.g., D5-half-NS) to the fluids and CONTINUE the insulin infusion. The dextrose lets you keep insulin running to clear ketones/close the gap without causing hypoglycemia. You may reduce the insulin rate slightly but do not stop it.

### BOARD TRAP

WRONG: 'Glucose dropped to 200, so discontinue the insulin drip.' The anion gap is usually still open; stopping insulin reopens ketogenesis. Discriminator: at glucose ~200 → ADD dextrose, KEEP insulin — resolution is defined by the gap, not the glucose.

## 9. Step 5 Bicarb not routine

### WHAT YOU SEE

Center-bottom: crossed-out bicarb bag, NOT ROUTINE IN DKA

### WHAT IT ENCODES

Rung 5: bicarbonate is NOT routine — insulin + fluids correct the acidosis by clearing ketoacids (each metabolized ketone regenerates bicarbonate). Reserve it for severe acidemia, pH <7.0 (some use <6.9), where cardiac contractility and pressor responsiveness are impaired. Give as a slow infusion, never a rapid push.

### BOARD TRAP

WRONG: 'pH is 7.1 — give bicarbonate to speed correction.' No benefit at pH >7.0, and it adds harm. Discriminator: the ONLY bicarb indication in DKA is pH <7.0; moderate acidosis resolves with insulin and fluids alone.

## 10. Bicarb risks

### WHAT YOU SEE

Center-bottom: bicarb vial labeled pH 7.0, BICARB ONLY pH <7.0

### WHAT IT ENCODES

Why bicarbonate is avoided: it worsens HYPOKALEMIA (drives K<sup>+</sup> intracellularly), causes a PARADOXICAL CSF/CNS acidosis (CO<sub>2</sub> generated crosses the blood-brain barrier faster than bicarbonate), promotes arrhythmias, delays ketone clearance, can cause rebound metabolic alkalosis, and increases cerebral-edema risk in children.

### BOARD TRAP

WRONG: 'Bicarbonate is harmless and at worst just doesn't help.' It actively causes hypokalemia, paradoxical CNS acidosis, and pediatric cerebral edema. Discriminator: bicarb is potentially harmful, which is precisely why it's withheld unless pH <7.0.

## 11. Step 6 Transition / anion gap closed

### WHAT YOU SEE

Bottom-RIGHT corner: ANION GAP CALCULATOR, CHECK ANION GAP FIRST not glucose, RESOLUTION = correction not glucose

### WHAT IT ENCODES

Rung 6: stop the IV insulin only after RESOLUTION — anion gap closed (and HCO<sub>3</sub><sup>-</sup> ≥15-18, pH >7.3, patient eating). DKA resolution criteria are gap/bicarb-based, NOT a normal glucose. Before stopping the drip, give long-acting SC (basal) insulin and OVERLAP it with the infusion for 1-2 hours so a basal level is established when the drip comes off.

### BOARD TRAP

WRONG: 'The glucose normalized, so stop the IV insulin now.' Glucose normalizes long before the gap closes; stopping early causes rebound DKA. Discriminator: transition is triggered by gap closure (not glucose) and requires SC overlap before the drip stops.

## 12. Prevent rebound DKA

### WHAT YOU SEE

Bottom-center transition: must add dextrose / continue coverage so glucose-normal does not stop insulin (prevent rebound)

### WHAT IT ENCODES

IV regular insulin has a very short half-life (~minutes); if the drip is stopped before SC basal insulin has taken effect, insulin levels crater and ketoacidosis rebounds. Give SC basal (e.g., glargine) and overlap with the infusion for 1-2 hours (rapid-acting nutritional insulin overlaps ~15-30 min) so coverage is continuous.

### BOARD TRAP

WRONG: 'Turn off the drip and give the first SC dose at the same moment.' The gap between drip-off and SC onset reopens ketogenesis. Discriminator: SC insulin must be given 1-2h BEFORE stopping the IV drip — no insulin-free gap.

## 13. Complications: cerebral edema

### WHAT YOU SEE

RIGHT HHS fluid panel: REPLACE SLOWLY - TOO RAPID WORSENS NEUROLOGIC STATUS (over-rapid osmolar correction warning)

### WHAT IT ENCODES

Cerebral edema is the most feared, leading cause of DKA death in CHILDREN, caused by over-rapid fluid/osmolar correction (rapid drop in glucose/osmolality shifts water into brain cells). Prevention: avoid the insulin bolus in kids, lower glucose no faster than ~50-100 mg/dL/hr, and correct osmolality gradually. Onset: headache, lethargy, bradycardia/HTN (Cushing), declining consciousness 4-12h into treatment → give mannitol/hypertonic saline.

### BOARD TRAP

WRONG: 'In pediatric DKA, correct fluids and glucose as fast as possible to fix the acidosis quickly.' Aggressive/rapid correction precipitates fatal cerebral edema. Discriminator: in children, go SLOW (no bolus, controlled osmolar correction) — speed kills here.

## 14. Complications: hypoglycemia/hypoK/hypophos/HcMA

### WHAT YOU SEE

RIGHT HHS panel electrolyte/fluid warnings: 0.45% saline switch Na>150, slow replacement, large-deficit complications

### WHAT IT ENCODES

Treatment-related complications: HYPOGLYCEMIA (from continuing insulin — prevent by adding dextrose at glucose ~200); HYPOKALEMIA (insulin/bicarb shift K<sup>+</sup> in — replace proactively); HYPOPHOSPHATEMIA (insulin drives phosphate intracellularly — replace only if severe <1.0 mg/dL or with cardiac/respiratory/muscle weakness); HYPERCHLOREMIC NON-GAP ACIDOSIS (from large-volume NS resuscitation — expected, benign, self-resolves).

### BOARD TRAP

WRONG: 'A persistent acidosis after the anion gap has closed means the DKA is not resolved — restart aggressive insulin.' A post-treatment NON-gap (hyperchloremic) acidosis from NS is benign and self-limited. Discriminator: check the gap — if it's closed, a residual non-gap acidosis is the saline artifact, not ongoing DKA.
